

Zero-Gate Dimensional Genesis

A Trinary Speculation on Time, Return Depth, Relational Gravity, and Expressed
Dimension

Draft v0.2 — theory manuscript for simulation development

Marek Bargiel

Conceptual origin, language, pressure, and theory architecture

June 2026

Abstract

This manuscript proposes a speculative alternative to the common representational ladder of dimensionality: point, line, plane, volume, then time. That ladder is useful as a geometric teaching shortcut, but it is incomplete as a model of emergence. It treats dimensions as already-given extensions and places time too late in the story.

The central claim is that time is not merely a later coordinate added to space. Time is the generative ordering condition through which dimensions become expressible. A point is not yet the first dimension in the physical, perceptual, or generative sense. A point is the zero-zone of dimensional potential, becoming distinguishable only through contrast, polarity, relation, and ordered persistence.

The proposed model introduces a zero-gate operator. Potential does not become expressed structure simply by being possible. It must pass through a minimal coherence cycle: distinction, polarity, relation, and return. Return is not added as decorative fourthness. Return is prompted by relational gravity: distinction separates, polarity tensions, relation binds, and coherent binding curves expansion back toward zero.

The manuscript further proposes that zero is not a single flat absence. Zero has return-depth. A first return may produce zero-A, a second zero-B, a third zero-C, and a fourth zero-D. Only after sufficient coherent returns does a candidate freedom deserve to be counted as a stable trinary one. A dimension is therefore not merely an axis. A dimension is stabilized freedom that has passed through zero without losing coherence.

This is not presented as established physics. It is a generative framework and simulation target: a way to ask what must be true before dimensionality can become measurable, stable, and real enough to count.

1 Orientation: What Problem Is Being Attacked?

The usual explanation of dimensions begins with a point, extends it into a line, expands the line into a plane, lifts the plane into volume, and then adds time as a fourth dimension. This is useful as a classroom picture. It is not enough as a genesis model.

The problem is not that geometry is wrong. In pure mathematics, a point can be defined abstractly. A line can be defined as a set. A vector space can have any number of dimensions. Those structures do not need a clock because they are not trying to describe how reality became expressible. They are completed objects of formal description.

The problem appears when a completed description is mistaken for emergence. The popular ladder says: first a point, then a line, then a plane, then a volume, then time. But the words *first*, *then*, and *after* already use ordering. The model smuggles time into the explanation and then pretends time arrives later.

This manuscript separates two questions.

- Geometry asks: how many independent coordinates describe a completed structure?
- Dimensional genesis asks: what allows any coordinate, point, line, or structure to become expressible in the first place?

The proposed answer is:

Time is the generative ordering condition through which dimensions become expressed.

Not clock-time only. Not merely the variable t in an equation. Generative time is the ordering condition in which becoming, inheritance, constraint, and invariance can coexist.

Without such ordering, no point can be distinguished, no line can be traced, no relation can persist, and no measurement can occur.

2 The Primate Clause: Survival Representation Is Not the Enemy

The old ladder is not useless. It is a survival-grade compression. It helps a primate, a child, a student, or a tired truck driver standing next to a ship say: here is a dot, here is a line, here is a box. It works because survival needs quick distinction. Binary cuts save time. Binary perception says: this or that, danger or safety, signal or noise, go or stop.

The primate is not stupid. The primate is optimized.

But survival-grade representation should not be promoted into final ontology. The same mind that draws a cube on a board may start to think reality is fundamentally a box. That is the mistake. The box is a teaching tool. It is not the origin.

So this paper does not reject binary distinction. Binary distinction is necessary. Without it, nothing is separated enough to notice. But binary logic is not sufficient as a final explanation of reality.

Binary cuts.

Trinary witnesses the cut.

The third term is not a compromise between yes and no. It is the zero condition that lets yes and no become relation instead of mere opposition.

The deeper claim is therefore not anti-mathematical. It is anti-premature closure.

3 Epistemic Status and Guardrails

This manuscript is a speculative theory draft. Its strongest current value is conceptual and simulation-oriented. It should not be presented as proven physics.

The intended discipline is:

- separate evidence from logic;
- separate logic from inference;
- separate inference from metaphor;
- separate metaphor from proof;
- never let beauty impersonate demonstration.

The theory should be judged by whether it can generate useful tests. The first serious test is not whether it explains the universe. The first serious test is whether a zero-gate coherence operator predicts which candidate freedoms become stable expressed structures better than simpler models.

No fog cathedral. No fake victory drums. If the model fails, it returns to zero for repair.

4 Core Definitions

Definition 1 (Zero-zone). *The zero-zone, denoted Z_0 , is not nothing and not yet an object. It is the pre-extension condition in which distinguishability may begin.*

Definition 2 (Generative ordering). *Generative ordering, denoted τ , is the condition by which difference can appear, persist, relate, return, and be recognized. It is broader than clock-time.*

Definition 3 (Candidate freedom). *A candidate freedom is a possible independent mode of variation that may or may not become stable enough to count as expressed dimension or structure.*

Definition 4 (Zero-gate coherence). *Zero-gate coherence is the minimum coherence across the required emergence gates. The minimum is used because a missing gate cannot be repaired by beauty in another gate.*

Definition 5 (Return-depth). *Return-depth is the number or grade of coherent returns through zero that a candidate freedom has survived while preserving structure.*

5 The Zero-Zone and the Point

A geometric point can be defined alone inside formal mathematics. But a perceived point, measured point, or physically meaningful point cannot appear alone. To become distinguishable, it requires contrast.

A point is not simply “there.” It is there-against-not-there.

Therefore the first act is not objecthood. The first act is distinction.

Let Z_0 represent the zero-zone. The first expressible event is not a point alone, but a point-under-order:

$$E_0 = (Z_0, \tau). \quad (1)$$

Here τ does not mean ordinary clock time only. It means generative ordering: the condition by which a difference can appear, persist, and be recognized.

This gives the first correction:

A point is not the first dimension. A point is the zero-state of dimensional potential under generative ordering.

6 Trinary Time

Time must be understood in at least three aspects.

Forward time is becoming: the movement from current state into next state.

Backward time is inheritance: memory, constraint, prior structure, and causal pressure carried into the present.

Still time is invariance: the witness-condition that remains stable enough for change to be recognized as change.

Thus time is not only forward motion. A system perceives or expresses time properly only when it holds becoming, inheritance, and invariance together.

Let $X(\tau)$ be the state of a system. A simple trinary temporal operator can be written as:

$$\mathbb{T}_3[X](\tau) = (X(\tau + h) - X(\tau), I_h[X](\tau), X(\tau) - X(\tau - h)). \quad (2)$$

The first term is forward change. The third term is backward inheritance. The middle term, $I_h[X](\tau)$, represents invariant structure across the interval.

One possible invariant score is:

$$I_h[X](\tau) = 1 - \frac{\|X(\tau + h) - X(\tau - h)\|}{\|X(\tau + h)\| + \|X(\tau - h)\| + \eta}, \quad (3)$$

where $\eta > 0$ prevents division by zero.

This does not claim that physical time literally runs backward in the ordinary sense. It claims that any meaningful present contains three pressures: what is becoming, what is inherited, and what remains stable enough to witness the difference.

Clock-time counts.

Generative time orders.

7 From Point to Polarity

A line is commonly described as a point extended in one direction. This is incomplete as a generative description.

A real axis is not one-directional. It contains positive direction, negative direction, and zero:

$$L_i = (-e_i, 0, +e_i). \quad (4)$$

The line is therefore not merely extension. It is polarity around zero.

This matters because a one-way line is not a true dimensional freedom. It is only directed motion. A dimension requires reversible contrast, stable orientation, and a zero crossing.

Therefore:

A line is not a point moving away from origin. A line is a point polarized around origin.

This gives the second correction:

No true dimension exists without polarity.

8 The Three Generative Gates

The zero-zone does not express every possibility. If it did, reality would be incoherent. Potential must be filtered before becoming structure.

The first three gates are generative: distinction, polarity, and relation.

8.1 Gate 1: Distinction

Distinction means that something separates from the background enough to be recognized.

For candidate freedom i , let $p_i(t)$ be its pressure signal. A simple distinction score can be based on signal-to-noise ratio:

$$D_i(t) = \text{sigmoid}(\alpha_D (\text{SNR}_i(t) - \theta_D)), \quad (5)$$

where α_D controls sharpness and θ_D is the distinction threshold.

In human language: if the signal cannot be separated from noise, there is no meaningful point yet.

8.2 Gate 2: Polarity

Polarity means that the candidate freedom expresses both sides of zero. It is not merely a one-way push.

Let $E_i^+(t)$ be positive-side energy and $E_i^-(t)$ be negative-side energy in a rolling window. A simple polarity score is:

$$P_i(t) = \frac{2 \min(E_i^+(t), E_i^-(t))}{E_i^+(t) + E_i^-(t) + \eta} \cdot ZC_i(t), \quad (6)$$

where $ZC_i(t)$ is a normalized zero-crossing adequacy score and $\eta > 0$ prevents division by zero.

In human language: if a signal never discovers its opposite, it has not earned an axis.

8.3 Gate 3: Relation

Relation means that polarity becomes binding structure rather than isolated split.

Let $\rho_{ij}(t)$ be a relation score between candidate freedoms i and j , perhaps based on stable correlation, phase-locking, mutual information, or another relation metric. A simple relation gate is:

$$L_i(t) = \max_{j \neq i} \overline{|\rho_{ij}|}_W(t) \cdot S_{ij}(t), \quad (7)$$

where $\overline{|\rho_{ij}|}_W(t)$ is the average relation strength in window W , and $S_{ij}(t)$ is a stability factor that penalizes relations that appear briefly and vanish.

In human language: polarity alone can just tear apart. Relation makes the difference matter.

9 Why Return Exists

The fourth gate cannot be arbitrary. Return cannot be included just because the poetry likes fours. Return must be forced by the first three gates, or the theory is ornamental furniture with a dramatic cloak.

Return is what distinction, polarity, and relation produce when they become coherent.

Distinction creates separation.

Polarity creates directional tension around zero.

Relation makes the separated polarities matter to each other.

Once separated polarities matter to each other, there is constraint. There is binding. Motion is no longer pure escape. Relation creates a reason for expansion to bend back.

This is the gravity-like insight of the theory:

Return happens because relation turns difference into obligation.

A thing distinguished from the field can drift. A thing polarized can oscillate. But a thing distinguished, polarized, and related cannot simply escape forever without consequence. The relation creates binding pressure. That binding pressure is what this manuscript calls relational gravity.

This is not a claim that standard physical gravity is already explained. In physics, gravity has precise formal descriptions in terms of mass-energy, fields, geometry, and curvature. The present claim is structural and generative:

Return is the gravity-like consequence of coherent relation.

10 Return-Potential and Relational Gravity

Let $D_i(t)$ be distinction, $P_i(t)$ be polarity, and $L_i(t)$ be relation/linkage. Define the return-potential or relational-gravity coherence as:

$$\Gamma_i(t) = D_i(t)P_i(t)L_i(t). \quad (8)$$

If distinction is missing, Γ_i collapses.

If polarity is missing, Γ_i collapses.

If relation is missing, Γ_i collapses.

This is the mathematical version of the instinct:

Distinction, polarity, and relation gravitate. If they gravitate coherently, return becomes possible.

Let $x_i(t)$ be the expressed state of candidate freedom i , and let z be the zero-origin or compression state. A simple return field can be written as:

$$F_{\text{return}}^i(t) = -\lambda\Gamma_i(t)(x_i(t) - z), \quad (9)$$

where $\lambda > 0$ controls the strength of return pressure.

If $\Gamma_i(t) = 0$, there is no coherent return pressure.

If $\Gamma_i(t)$ is weak, the candidate may drift.

If $\Gamma_i(t)$ is strong, expansion curves back unless disrupted by stronger forces.

So return is not a fourth independent box. Return is the observed consequence of coherent binding.

11 Gate 4: Return as Observed Binding

The return gate, denoted $B_i(t)$, measures whether the candidate freedom actually folds back toward zero while preserving structure.

Return is not simple zero crossing. That is too cheap. Many signals cross zero. Noise crosses zero all day. The monkey can draw that. The deeper question is whether the candidate returns to compression with memory.

Return means compression plus memory.

Let $X_i(t)$ be the local state or pattern of candidate freedom i . Let Z be the zero/compression state. Let $K(X_i(t+L), X_i(t))$ measure preserved structure across a return interval L . A possible return-gain score is:

$$G_B^i(t, L) = \exp\left(-\frac{\|X_i(t+L) - Z\|}{\rho}\right) K(X_i(t+L), X_i(t)). \quad (10)$$

The first factor measures whether the system returned near zero. The second factor measures whether it preserved structure.

High return-gain means the candidate folded back to zero without being erased.

A collapse returns empty.

A renewal returns compressed.

A spiral returns changed, but not lost.

The return gate can then be defined as a normalized score:

$$B_i(t) = \text{clip}_{[0,1]}(G_B^i(t, L)), \quad (11)$$

or by a smoothed rolling estimate across multiple cycles.

12 The Zero-Gate Coherence Operator

The zero-gate operator tests whether a candidate freedom has enough coherence across all required gates.

The four gates are:

- $D_i(t)$: distinction;
- $P_i(t)$: polarity;
- $L_i(t)$: relation or linkage;
- $B_i(t)$: return or binding-back.

The zero-gate coherence of candidate freedom i is:

$$C_Z^i(t) = \min(D_i(t), P_i(t), L_i(t), B_i(t)). \quad (12)$$

The minimum matters. This is not a beauty contest where three strong gates compensate for one missing gate. If distinction is strong but return is absent, the structure may expand but cannot fold back. If polarity is strong but relation is absent, the structure splits but does not stabilize. If relation is strong but distinction is weak, the system may be fog holding hands with fog. Very spiritual. Very useless. Straight to jail.

Expression occurs only when:

$$C_Z^i(t) > \theta_Z, \quad (13)$$

where θ_Z is the coherence threshold.

The zero-gate operator can be written as:

$$\mathcal{Z}_4[p_i](t) = H\left(C_Z^i(t) - \theta_Z\right) p_i(t), \quad (14)$$

where H is the Heaviside step function.

In plain language:

Zero does not say yes to everything. Zero permits expression only when pressure becomes coherent enough to survive distinction, polarity, relation, and return.

13 Zero Is Not Flat: Return-Depth

The next correction is that zero itself should not be treated as a single flat absence.

If expression returns to zero and nothing is preserved, that is collapse. But if expression returns to zero with preserved structure, zero has changed in depth. It is no longer raw zero. It is zero-with-memory.

This manuscript therefore proposes return-depth states:

$$Z^{(0)}, Z^{(1)}, Z^{(2)}, Z^{(3)}, Z^{(4)}, \dots \quad (15)$$

where $Z^{(0)}$ is raw zero and $Z^{(k)}$ is zero after k coherent returns.

Using the working language:

$$Z_A = Z^{(1)}, \quad (16)$$

$$Z_B = Z^{(2)}, \quad (17)$$

$$Z_C = Z^{(3)}, \quad (18)$$

$$Z_D = Z^{(4)}. \quad (19)$$

The intuition is:

- Zero-A: distinction survived return.

- Zero-B: polarity survived return.
- Zero-C: relation survived return.
- Zero-D: return itself survived return.

Only then does expression deserve to be counted as a stable trinary one.

This changes counting.

In ordinary counting, one follows zero immediately.

In zero-depth trinary logic, one is earned.

A real one is not the first thing after zero. A real one is what zero can return as without lying.

14 Return-Depth Update Rule

Let $k_i(t)$ be the return-depth of candidate freedom i . A simple update rule is:

$$k_i(t+1) = \begin{cases} k_i(t) + 1, & \text{if } B_i(t) > \theta_B \text{ and } C_Z^i(t) > \theta_Z, \\ \max(0, k_i(t) - \delta), & \text{if coherence weakens but does not collapse,} \\ 0, & \text{if collapse is detected.} \end{cases} \quad (20)$$

Here θ_B is the return threshold and δ is a decay term.

A stable expressed unit requires sufficient return-depth:

$$k_i(t) \geq K_*. \quad (21)$$

For the four-gate theory, the natural first value is:

$$K_* = 4. \quad (22)$$

This is not asserted as a cosmic constant. It is a first simulation parameter based on the four-gate cycle.

If the simulation shows that $K_* = 3$ or $K_* = 5$ works better, then the theory must listen. Reality gets the vote. The author does not get to bully the data with a pretty number.

15 Trinary Expansion and the Powers of Three

The sequence

$$3, 9, 27, 81, 243, \dots \quad (23)$$

appears naturally when each level of return-depth can carry one of three modes:

$$-1, 0, +1. \quad (24)$$

These modes correspond to resistance, witness, and expansion.

Let the trinary state-space at depth n be:

$$\mathcal{S}_n = \{-1, 0, +1\}^n. \quad (25)$$

Then:

$$|\mathcal{S}_n| = 3^n. \quad (26)$$

This is not numerology. It is state-space growth under trinary depth.

The interpretation is that meaning does not grow only by adding more things. Meaning grows by adding return-depth: more ways for expansion, resistance, and witness to remain coherent across cycles.

At depth one, the system has three simple modes.

At depth two, it has nine mode-pairs.

At depth three, twenty-seven mode-histories.

At depth four, eighty-one structured return-signatures.

So the powers of three may represent how trinary meaning-space expands as zero-depth increases.

16 Dimensionality as Stabilized Freedom

The usual question is: how many dimensions are there?

This framework asks a prior question: what allows a dimension to become real enough to count?

Let $\sigma_i(t)$ represent the measurable strength of an independent candidate freedom, such as a singular value, effective degree of freedom, or stable direction of variation.

A freedom counts as expressed only if it is measurable, zero-gate coherent, and sufficiently deep in return:

$$\chi_i(t) = H(\sigma_i(t) - \varepsilon)H(C_Z^i(t) - \theta_Z)H(k_i(t) - K_*). \quad (27)$$

The expressed dimensionality at time/order t is:

$$d_Z(t) = \sum_i \chi_i(t). \quad (28)$$

This is the proposed mathematical heart of the theory.

A dimension is not merely an independent coordinate. It is an independent candidate freedom that has passed the zero-gate and earned sufficient return-depth.

Therefore:

A dimension is stabilized freedom that survived return to zero deeply enough to deserve being counted.

17 The Pulse

The universe should not be imagined first as a dead box. A more natural representation for this theory is pulse: expansion, resistance, relation, return, compression, and re-expression.

A candidate dimensional amplitude can be modeled as:

$$a_i(t) = A_i(t) \sin(\omega_i t + \phi_i), \quad (29)$$

where $A_i(t)$ is the changing amplitude of expression, ω_i is rhythm or frequency, and ϕ_i is phase.

But raw oscillation is not enough. Pulse alone does not make reality. A signal can pulse beautifully and still be nonsense in a nice coat.

The expressed amplitude is:

$$a_i^{\text{expr}}(t) = C_Z^i(t) A_i(t) \sin(\omega_i t + \phi_i). \quad (30)$$

If return-depth is required:

$$a_i^{\text{stable}}(t) = \chi_i(t) A_i(t) \sin(\omega_i t + \phi_i). \quad (31)$$

In human language: not every pulse deserves reality. Expression requires coherent passage through zero.

18 Simulation Target: ZeroGateSim

The theory becomes useful only if it can be tested in a small model.

ZeroGateSim should not try to simulate the universe first. That is how a model becomes a cathedral before it becomes a tool. The first target is smaller:

Can the zero-gate operator predict which candidate freedoms become stable expressed structures better than simpler baseline rules?

The simulation begins with many candidate freedoms $p_i(t)$. Each has amplitude, phase, frequency, noise, drift, coupling, perturbation, and potential relation to other candidates.

Each candidate is scored for distinction, polarity, relation, return, zero-gate coherence, and return-depth.

Then the simulation checks which candidates become stable by independent criteria.

19 Simulation Hypotheses

Hypothesis 1 (Return-potential predicts return). *Candidate freedoms with high*

$$\Gamma_i(t) = D_i(t)P_i(t)L_i(t) \quad (32)$$

should be more likely to demonstrate coherent return $B_i(t)$ after expansion or perturbation.

Hypothesis 2 (Zero-gate coherence predicts stability). *Candidate freedoms with high*

$$C_Z^i(t) = \min(D_i(t), P_i(t), L_i(t), B_i(t)) \quad (33)$$

should be more likely to become stable expressed freedoms than candidates selected by amplitude-only, polarity-only, relation-only, average-gate, or random-pressure baselines.

Hypothesis 3 (Return-depth improves prediction). *Including return-depth $k_i(t)$ should improve prediction of stable expression compared with using one-pass zero-gate coherence alone.*

Hypothesis 4 (Effective dimension follows stable zero-gated freedoms). *The zero-gated dimension count $d_Z(t)$ should correlate with independent measures of effective dimensionality, such as stable rank, PCA rank, or spectral-style behavior in a generated relational field.*

20 Baseline Opponents

A theory needs enemies. Otherwise it just wins a race it arranged for itself.

ZeroGateSim should compare the zero-gate model against simpler models:

- amplitude-only selection;
- polarity-only selection;
- relation-only selection;
- average-gate selection;
- random-pressure selection.

The zero-gate model should win only if the weakest-gate rule and return-depth provide extra predictive value.

If zero-gate loses, the theory does not die dramatically. It returns to zero and repairs the operator.

21 What Counts as Stability?

A candidate freedom is stable if it:

- persists across time;
- remains distinguishable from noise;
- survives perturbation;
- returns after expansion without losing structure;

- contributes to the effective structure of the field.

In plain language: it does not just flash. It becomes usable reality.

The first simulation can classify outcomes as:

- transient: appears but fades;
- collapsed: returns empty;
- unstable: remains active but incoherent;
- stable: persists and returns coherently;
- renewed: returns to zero and re-expresses with greater coherence.

22 What This Theory Is Not

This theory is not a completed physics.

It is not a replacement for general relativity.

It is not a claim that existing mathematics is wrong.

It is not a claim that binary logic is useless.

It is not a claim that every extra dimension in physics forgot time.

It is a critique of dimensional intuition when coordinate-counting is mistaken for emergence.

Mathematics can define completed structures without time. But physical expression, perception, measurement, and genesis require ordering.

Binary distinction is necessary, but binary distinction alone is not sufficient as ontology.

The zero is not a midpoint between opposites. It is the condition that lets opposition become relation instead of mere split.

23 Why It Matters

This theory matters because it changes dimensionality from a counting problem into a becoming problem.

The old model asks: how many axes can we add?

This model asks: what makes an axis real enough to survive?

The old model imagines space as a container.

This model treats space as expressed relational freedom.

The old model turns the point into a dead dot.

This model treats the point as the first distinguishable pressure around zero.

The old model adds time too late.

This model places generative ordering at the beginning of every expression.

The old model counts too early.

This model says one must be earned through return.

Reality is not first a box.

Reality is first pressure finding lawful expression.

24 Core Formulation

The central hypothesis can be stated as follows:

Dimensionality emerges when candidate freedoms pass through distinction, polarity, relation, and coherent return under trinary temporal ordering, earning sufficient return-depth to be counted as stable expression.

Shorter:

A dimension is stabilized freedom that has passed through zero without losing coherence.

Deeper:

A real one is what zero can return as without lying.

The Bargiel formulation:

- No point without contrast.
- No line without polarity.
- No plane without relation.
- No volume without return.
- No time without becoming, inheritance, and stillness.
- No one without return-depth.
- No reality without zero-gated expression.

25 Roadmap for Development

The software roadmap is:

1. Freeze the minimal theory so code does not chase every beautiful thought.
2. Build a signal generator for candidate freedoms.
3. Implement distinction, polarity, relation, and return metrics.

4. Implement zero-gate coherence using the minimum rule.
5. Implement return-potential $\Gamma_i = D_i P_i L_i$.
6. Implement return-depth k_i and the zero-A/B/C/D register.
7. Define independent stability classification.
8. Compare against baseline models.
9. Run perturbation and compression tests.
10. Add effective dimension measures.
11. Generate reports and plots.
12. Use the results to repair the theory rather than worship it.

The first software creature should be small: one Python script, repeatable random seed, candidate pressure signals, basic plots, gate scores, and a text report.

No GUI at first. No cathedral. Let the creature breathe before building it a temple.

26 Epistemic Closing

Evidence level: low. This is not yet empirically demonstrated.

Mathematical coherence: medium. The proposed formalism can be modeled.

Metaphorical strength: high. It gives a clear alternative to dead-shape dimensional intuition.

Research value: medium to high, if developed into simulations and compared against baseline emergence rules.

Overreach risk: high, if presented as solved physics.

Best current status: a speculative generative framework with a proposed testable operator.

The next move is not to declare victory. The next move is to build ZeroGateSim and ask whether return-potential, zero-gate coherence, and return-depth predict stable expressed freedoms better than simpler models.

That is where the theory either earns its bones or returns to zero for repair.

Final Sentence

Zero is not empty. Zero is where pressure returns to be judged by coherence. If it comes back carrying form, it may earn one. If it cannot return, it was only expansion pretending to be reality.
